

## 98. Family DROSOPHILIDAE

By Neal L. Evenhuis & T. Okada

Adults of most species of Drosophilidae are attracted to and feed upon a great variety of fermenting substances, hence the common name, vinegar, pomace, or fruit flies (the latter not to be confused with the true fruit flies of the family Tephritidae). Oviposition and larval breeding are, however, more highly specialized in fruits or flowers, slime fluxes, decaying leaves, or fungi. Some species are leaf mining, commensal, or even predatory. *Drosophila busckii*, a cosmopolitan species, has occasionally been bred from the leaves of lettuce in Victoria (Bock 1982) as well as from the leaves of the pea plant in Japan (Okada & Sasakawa 1956).

By the end of 1984, 62 genera and 2,822 described species of this family were known worldwide, and at least 4,000 species were predicted to exist (Wheeler 1986). This catalog records over 1,000 species in 65 genera and subgenera from the Australasian/Oceanian Regions.

Among the vast areas of the regions covered here, the Hawaiian Islands are the most remarkable in species diversification: 533 species in 9 genera are recorded from there, and more than 1,000 species are thought to exist. As early as 1958, E.C. Zimmerman stated that there might be as many as 300 species of Drosophilidae in Hawaii (an area smaller than the state of Massachusetts or less than one-fifth the size of Ireland). Hardy's (1965) descriptions and records of about 400 species of this family from the Hawaiian Islands has led a number of outstanding investigators to undertake

morphological, cytological, genetic, ecological, and biochemical studies in the Hawaiian Islands' natural laboratory of evolution.

Micronesia harbors 21 genera and 128 species, Australia 31 genera and 230 species, and New Zealand 2 genera and 14 species. New Guinea is the least surveyed area of the regions, currently possessing 22 genera and about 100 species. In each area listed above, half or more of the species belong to the genus *Drosophila*. This proportion corresponds to the figure given by Wheeler (1986) for the total world species. The genus next most speciose is *Scaptomyza* in the Hawaiian Islands, and *Leucophenga* and *Mycodrosophila* in Oceania, New Guinea, and Australia.

This catalog owes much to Wheeler's world catalog of Drosophilidae (1981) and its supplement (1986).

6. *Geographical equivalents*: Due to the nature of the areas covered by the catalog, many of the localities cited in early works are no longer used, and some are not easily found in gazeteers due to variations in spelling by Dutch, German, French, or other former administrators of the areas in question. This is especially true of islands and localities within and around the Indonesian Archipelago referred to by Walker in his series of papers on Diptera collected by A.R. Wallace. The following is a list of such localities plus obsolete variant names of localities that have recently changed their spelling. The names are listed alphabetically (in order of first appearance in either the first or second column). The old name or obsolete spelling is given in the first column, the current equivalent is given in the second column, and the format of listing in the distributional information of the catalog is given in the third column. The list is not exhaustive, but cites those most often encountered in the literature:
